HELPING HORSES THROUGH AI?

Equine Integration

Ugh... writing weekly feedback for every horse is so time-consuming 😩

We just want to support our clients faster.

Us

Totally get that 😅 – what if you didn't have to do it all manually?

Equine Integration

Wait... you can automate it? 👀How?

Us

Simple! You already track ACWR for each horse's exercise. With that + past client messages, AI can:

1. 🔍 Spot overtraining or undertraining
2. 🧪 Use ACWR to assess stress levels
3. 💬 Auto-generate personalized feedback

Example ➡

Horse Report

Name: Mr. Clip Clop
Breed: Hanoverian
Gender: Male
Age: 10

Walk (ACWR = 0.91)
→ In the optimal range. The horse is maintaining fitness in walking activity.

Canter (ACWR = 1.2)
→ Approaching higher intensity, but still within the healthy zone.

Galop (ACWR = 0.29)
→ Almost no recent gallop activity — fitness in this area may decrease.

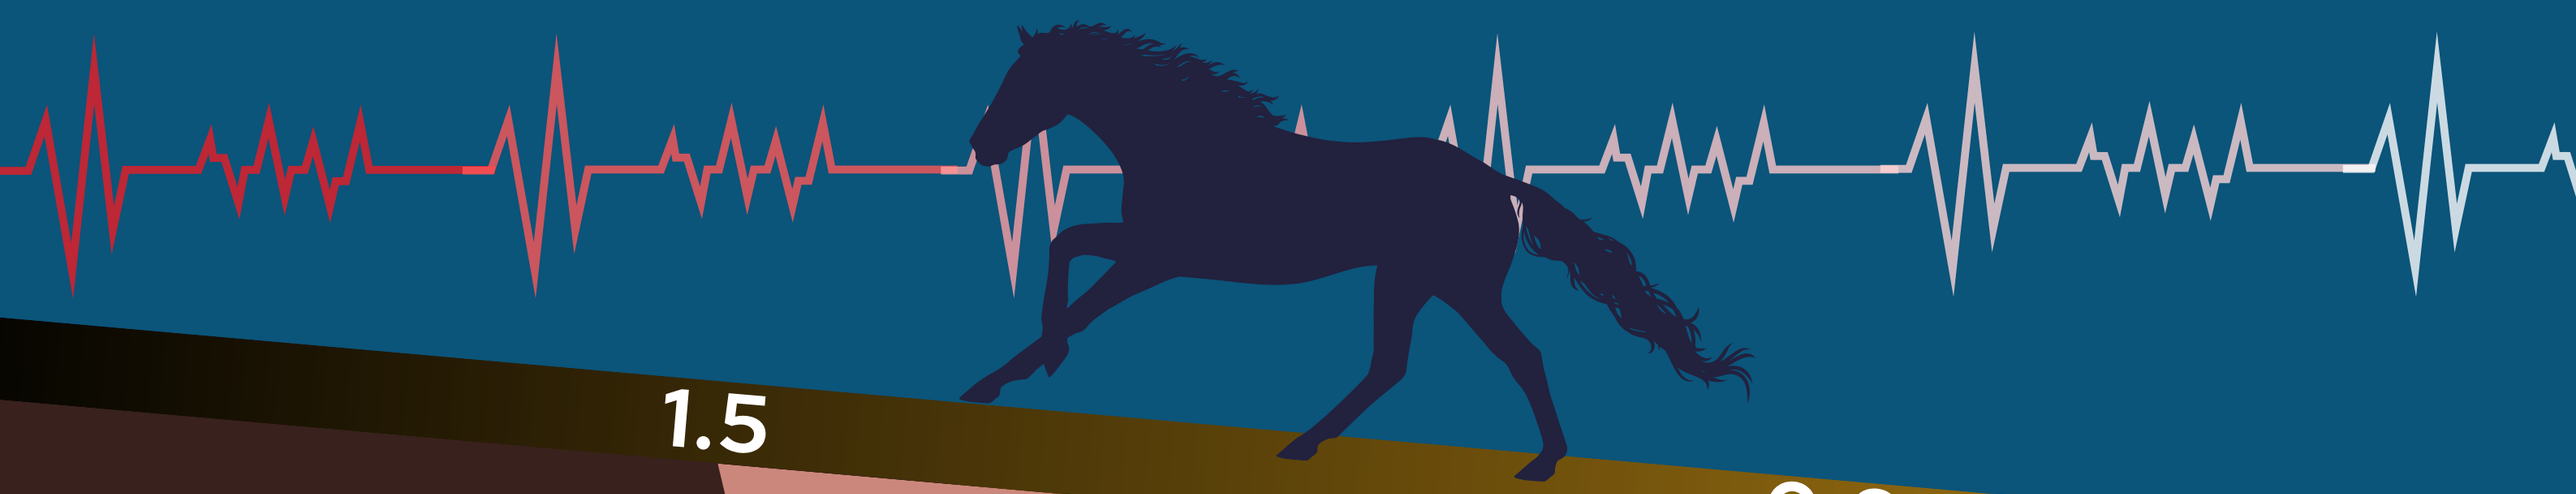

AI

"Your horse is showing a healthy training load in trot and canter, but **gallop engagement is minimal**. Consider gradually reintroducing sprint work to maintain full-range conditioning."

What is ACWR (Acute Chronic Workload Ratio)?

A measure that compares how much a horse has trained this week to how much they've trained on average in the past few weeks.

ACWR = Acute Load (7-day total) ÷ Chronic Load (3–4 week average)

1.5

Overtrained (Risk of injury)

Horse may be doing too much too quickly, increasing the risk of injury or fatigue. It's time to ease the workload and prioritize recovery.

Optimal zone for performance & health

Balanced and healthy training load! Horse is in the safe zone for both performance improvement and injury prevention. Keep it consistent!

0.8

Undertrained (Loss of fitness)

Horse is not training enough compared to its usual routine. This may lead to loss of fitness or reduced performance. Consider gradually increasing intensity.
